

WHY SNOWFLAKE?

Concepts and Snowflake Fundamentals

Agenda

Massively Parallel Processing (MPP) for “Big Data” and historical limitations

Snowflake Innovation₁ – separation of Storage and Compute

The “secret sauce”₂ – micro-partitions, global cloud services

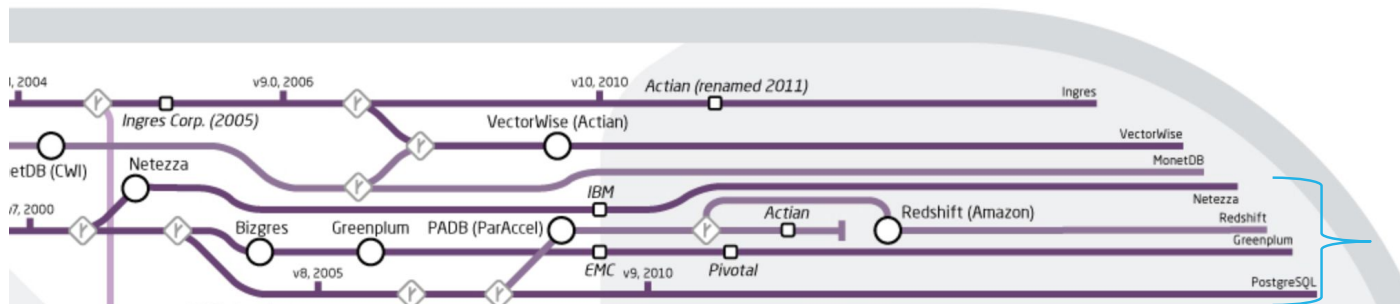

Some feature differentiators enabled by 1 and 2

The Snowflake AI Data Cloud High Level Architecture

Visualization using dashboards, Streamlit in Snowflake

MPP Architecture Evolution - PostgreSQL genealogy

<https://hpi.de/naumann/projects/rdbms-genealogy.html>

PostgreSQL descendants:

Netezza – forked PostgreSQL 7.2

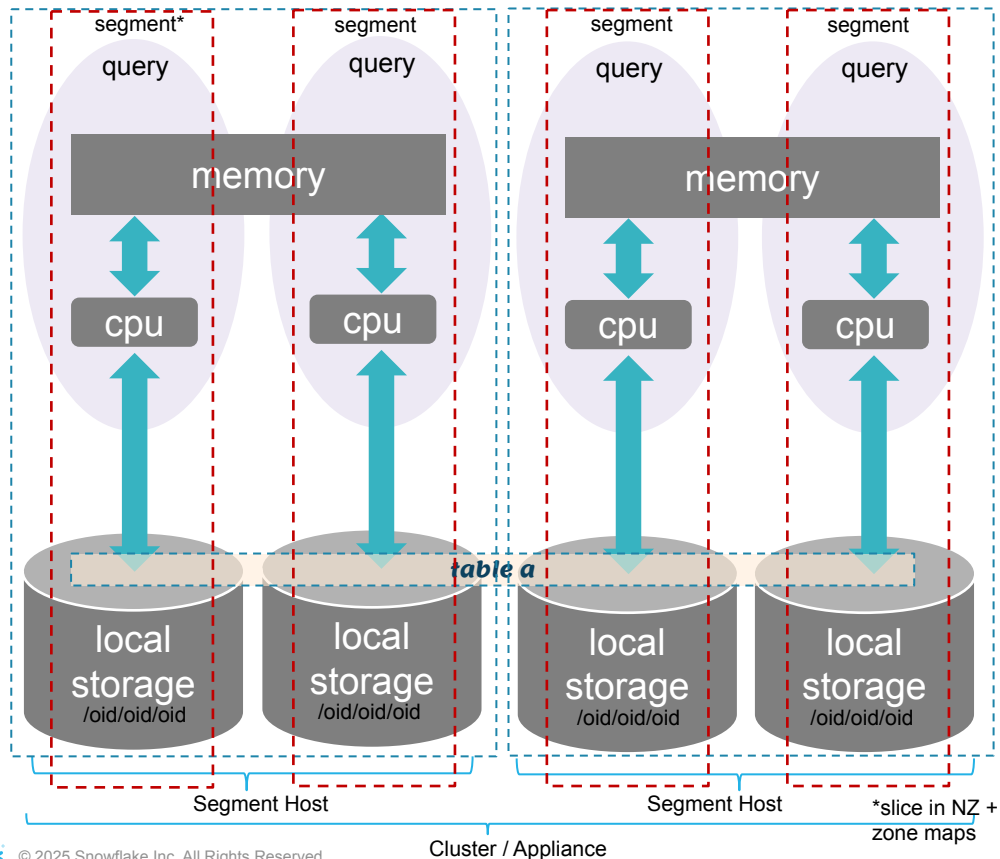

Greenplum – forked PostgreSQL v8.2

Redshift (as ParAccel) – forked PostgreSQL v8.0.2

How to build an MPP database from Postgres?

MPP Architecture of Greenplum / Netezza

Excellent performance on large table joins... as long as joins are “local”

Tightly-coupled Compute and Storage = “secondary” segments enforce data redundancy/durability

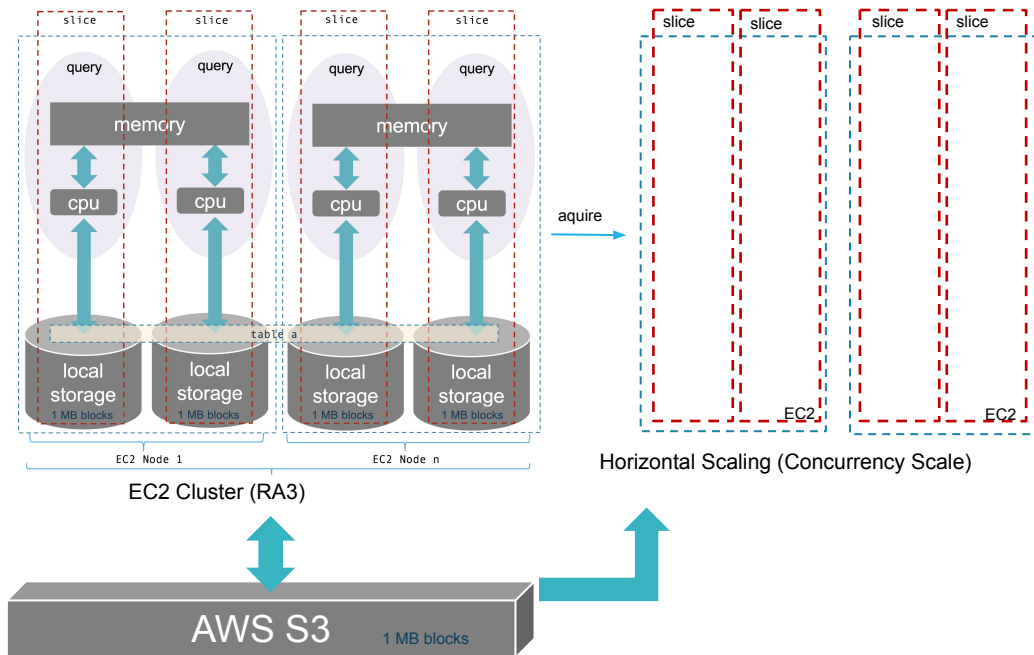

Skew! Data/static and processing/dynamic

Vacuum that bloat (table, catalog)

Maintenance Overhead

MPP Architecture of Redshift

No “idle” secondary slices but degree of parallelism fixed during cluster configuration

Tightly-coupled Compute and Storage = horizontal slow, vertical scaling worse (elastic vs classic resize)

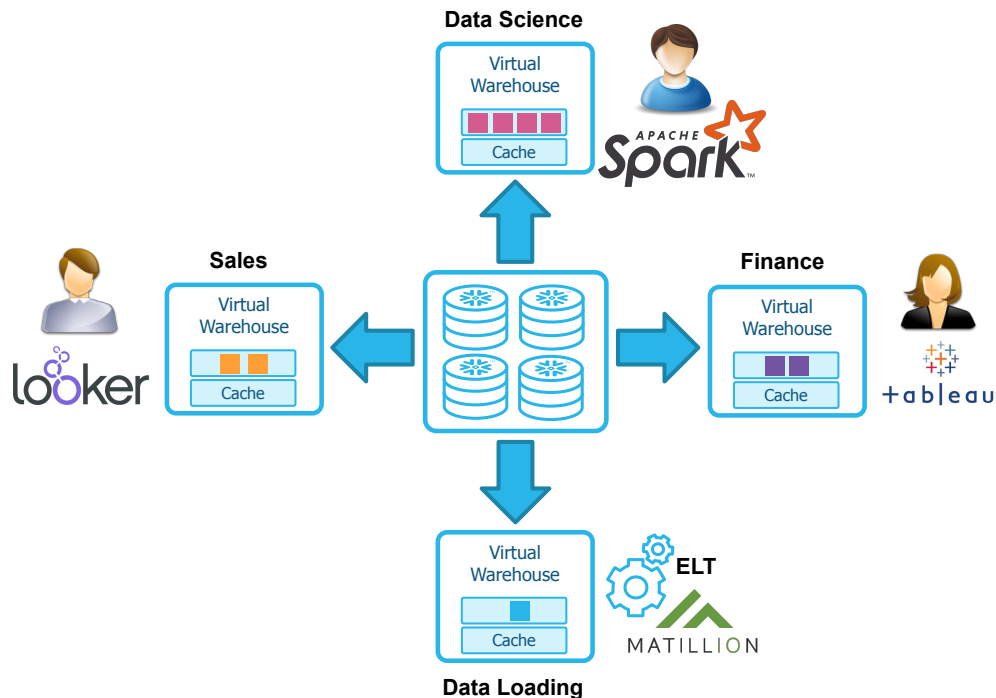

Skew remains... artifact of data distribution

Redshift Spectrum “extends” Postgres-derived engine but is also dated

Complex Workload Management₄

Snowflake separates Storage and Compute

No need to determine and commit size of compute cluster up-front, use t-shirt sized *virtual warehouses*

Need more compute power? Resize your virtual warehouse on the fly

Need more concurrency? Configure multi-cluster warehouse

Native support for open table formats

Simple maintenance, it just works!

Scale “up” for performance

```
alter warehouse PROD_VWH set  
warehouse_size = 'XLARGE';
```

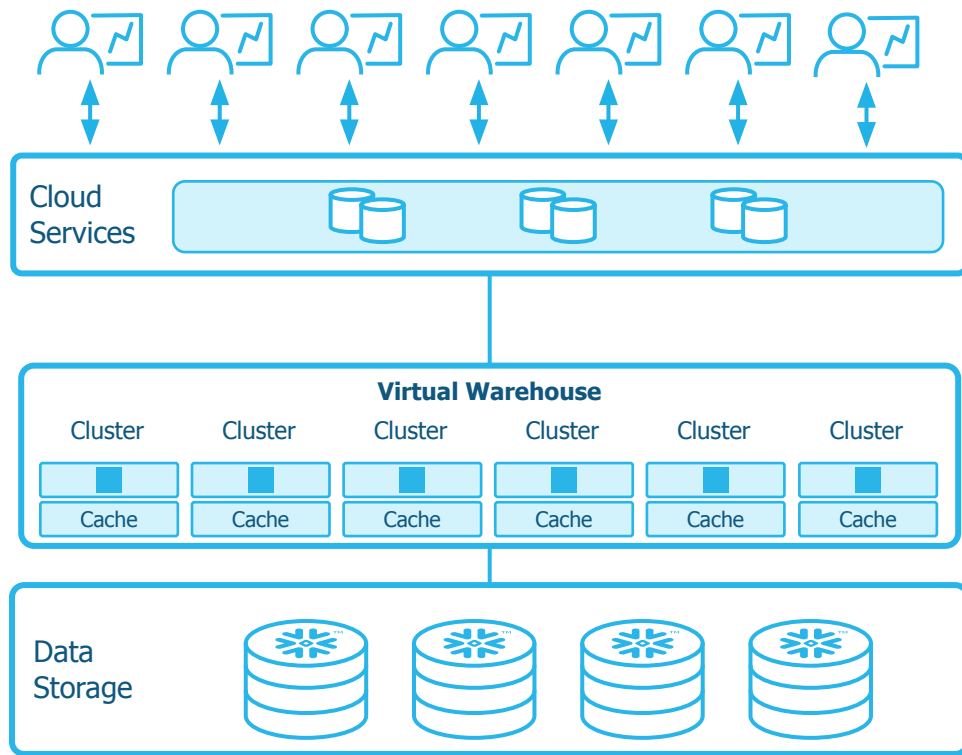

Scale Up

- X-Small – 1 Node
- X-Large – 16 Nodes

**Small VWH is suspended
when all queries
complete.**

Scale “out” for concurrency

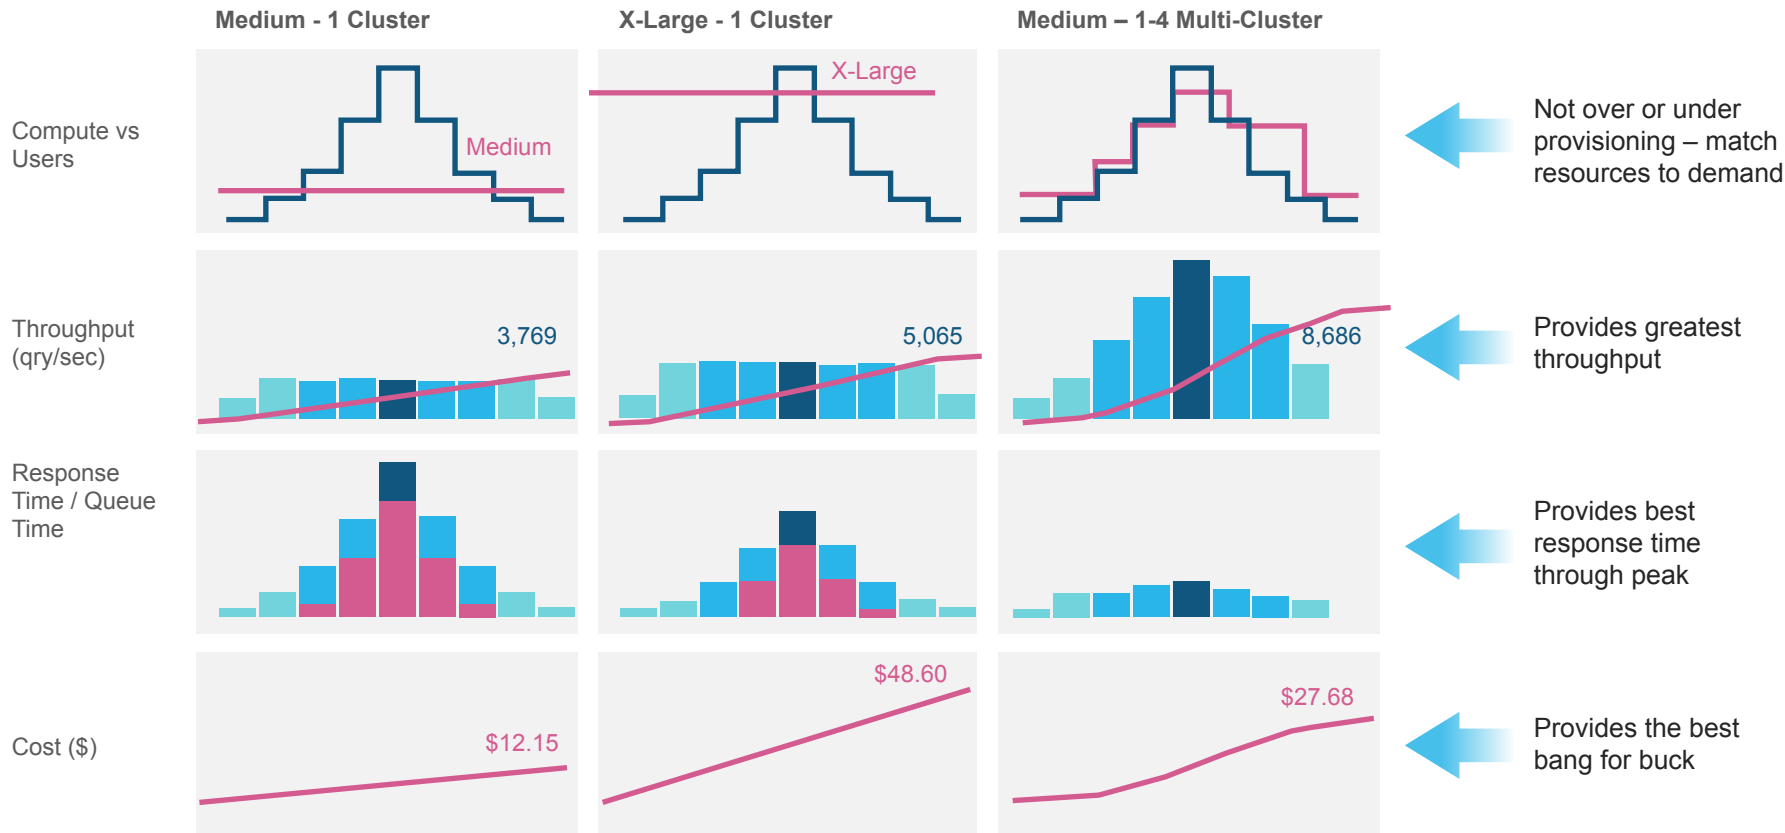

```
ALTER WAREHOUSE prod_wh SET  
  MIN_CLUSTER_COUNT = 1  
  MAX_CLUSTER_COUNT = 5;
```

Time Elapsed: 68ms

Automatically Scale Out
1 – 10 same size Clusters

Scale out optimization pattern

Secret sauce: Micro-partitions

Table: t1

Contains 50 MB and 500 MB of uncompressed data

Groups of rows in tables are mapped into individual micro-partitions, organized in a columnar fashion

Unlike traditional static partitioning, Snowflake micro-partitions are derived automatically

Size and structure allows for extremely granular pruning of very large tables

Micropartitions are immutable

Snowflake stores metadata about all rows stored in a micro-partition, including

- The range of values for each of the columns in the micro-partition.
- The number of distinct values.
- Additional properties used for both optimization and efficient query processing.

Micro-partitions – academic papers

FIGURE 1: The N-ary Storage Model (NSM) and its cache behavior. Records in *R* (left) are stored contiguously into disk pages (middle), with offsets to their starts stored in slots at the end of the page. While scanning age, NSM typically incurs one cache miss per record and brings useless data into the cache (right).

2.1 The N-ary Storage Model

Traditionally, the records of a relation are stored in slotted disk pages [29] obeying an n-ary storage model (NSM). NSM stores records sequentially on data pages.

FIGURE 3: Partition Attributes Across (PAX), and its cache behavior. PAX partitions records into minipages within each page. As we scan *R* to read attribute age, values are much more efficiently mapped onto cache blocks, and the cache space is now fully utilized.

What is it?

Reorganize table data to align with query patterns

Value

Process only the relevant data from large tables

Faster queries and fewer compute credits

No blocking / impact on DML

Cost

Credits for background clustering maintenance

Adaptive Caching

Metadata

Metadata cached for fast access during query planning

Data

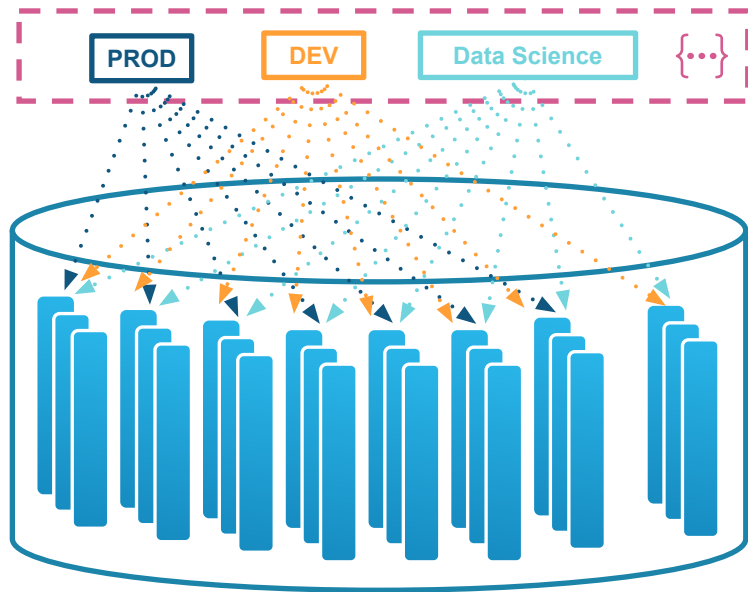

Active working set transparently cached on virtual warehouse SSD

Query results

Results sets cached for reuse without requiring compute (e.g., static dashboard queries)

Zero-Copy Cloning

The Metadata layer keeps track of every micro-partition file in every customer database.

Creating a DEV environment usually means copying the PROD database

Limited to subset of full Prod

Up to 2x storage requirement

Periodic refreshes

Snowflake Zero-Copy Clones

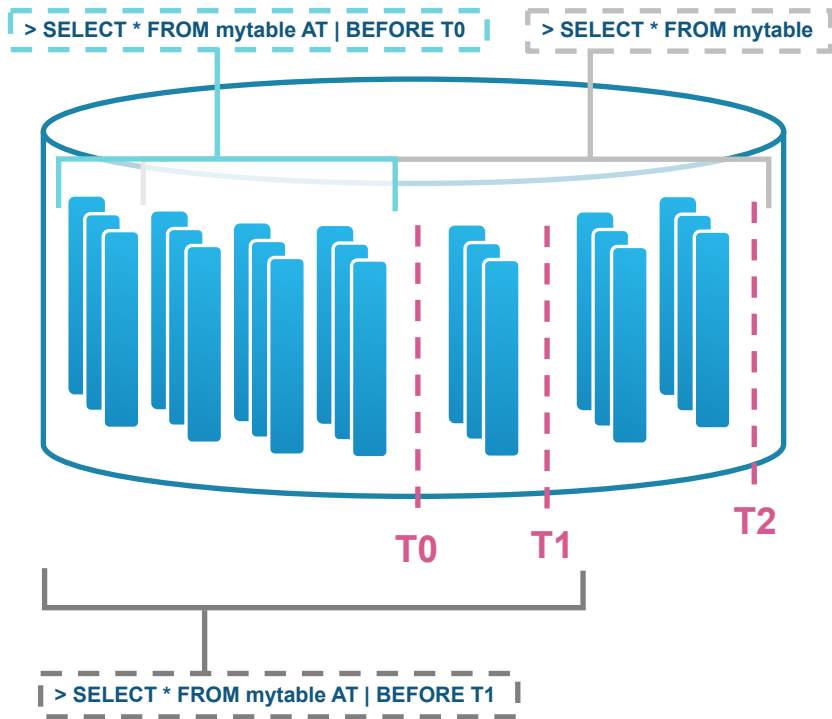

Simply “point” to the same files

Consumes zero additional storage

Changes to either DB are isolated

Time Travel

T0 – Initial state of database

T1 – update myTable set
colX = Y where...

T2 – ELT job loads new data

**Previous versions of data
automatically retained**

AT | BEFORE [timestamp | statement | offset]

CLONE AT | BEFORE to recreate a prior version

UNDROP recovers from accidental deletion

Accessed via SQL extensions

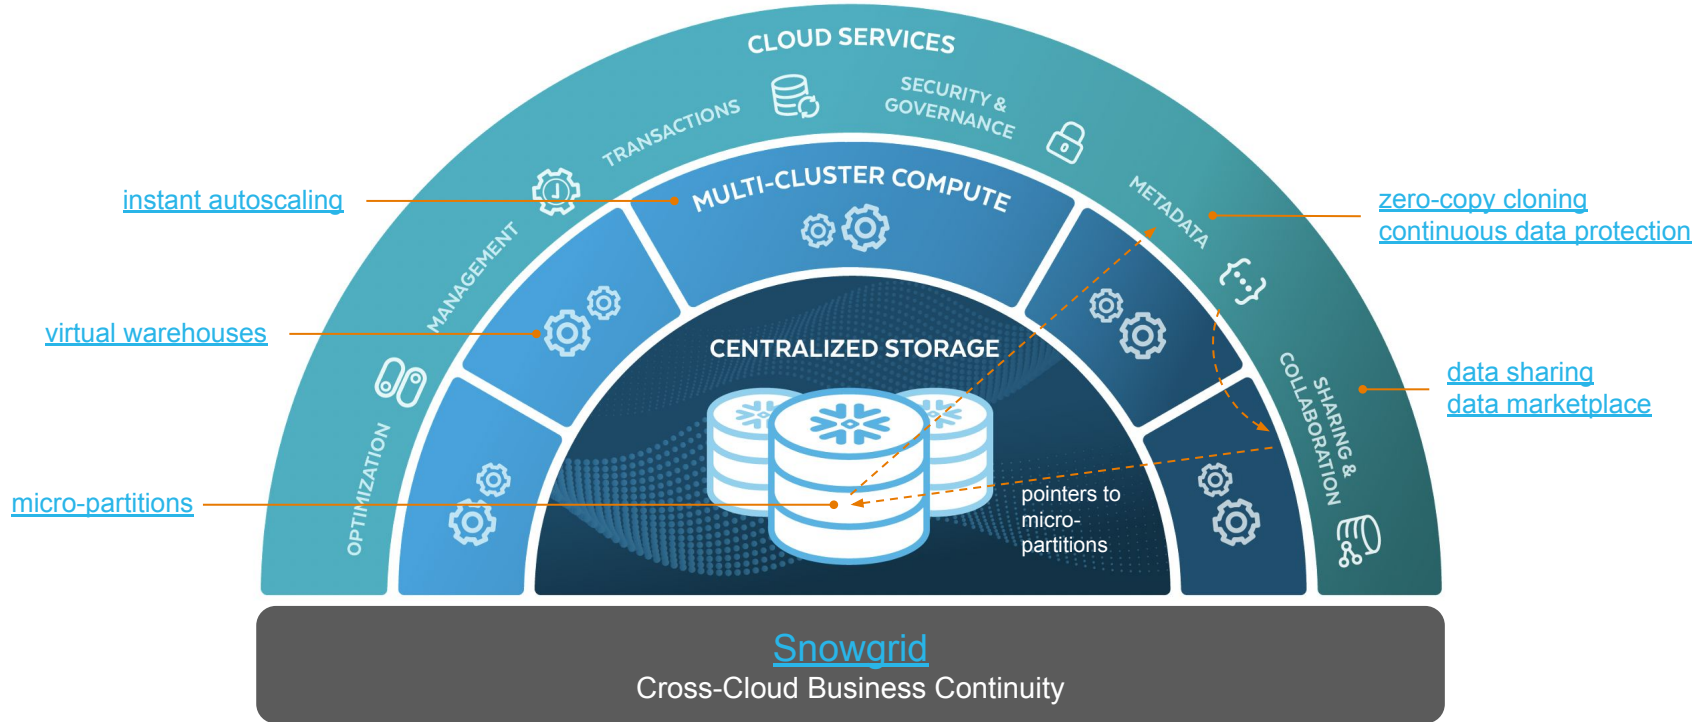

AT | BEFORE [timestamp | statement | offset]

CLONE AT | BEFORE to recreate a prior version

UNDROP recovers from accidental deletion

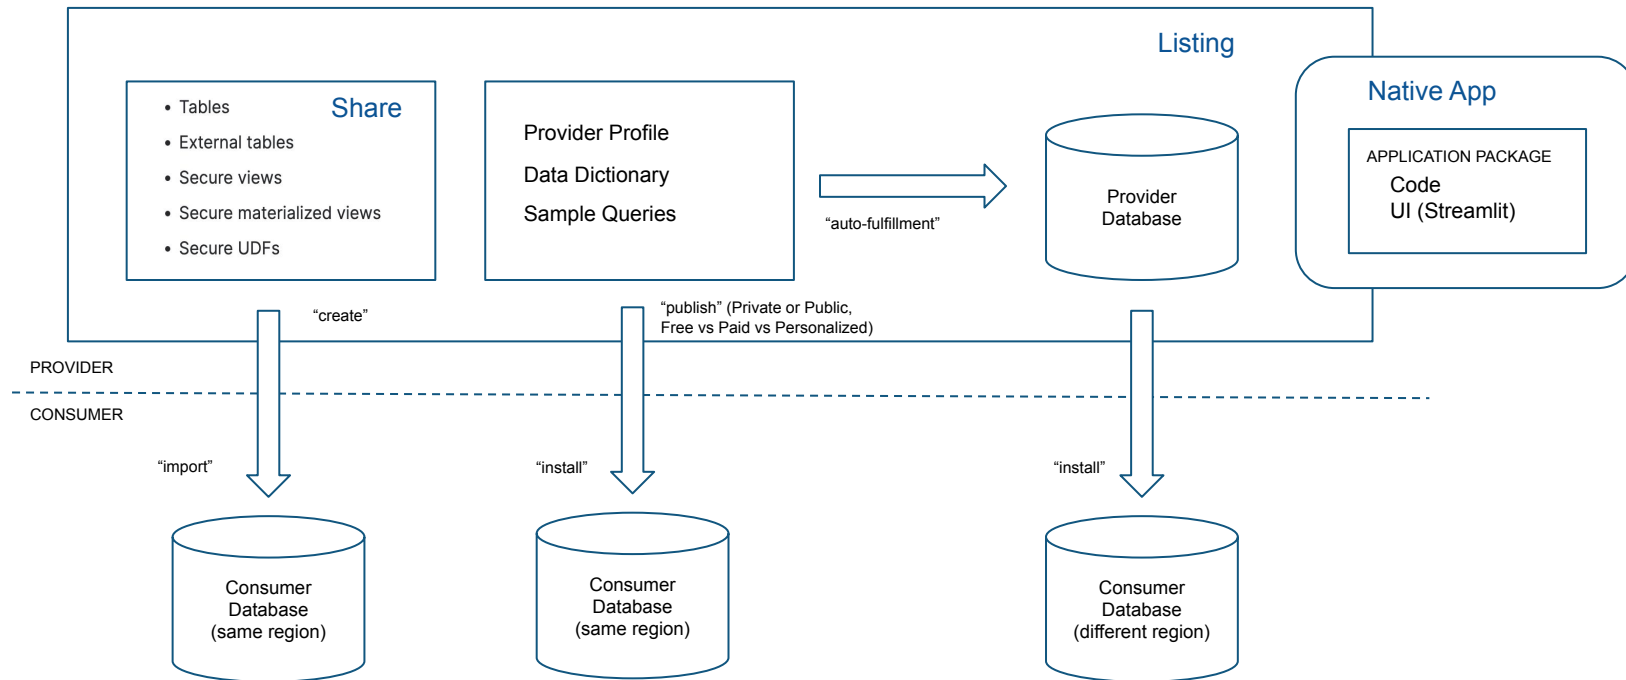

Snowflake Architecture

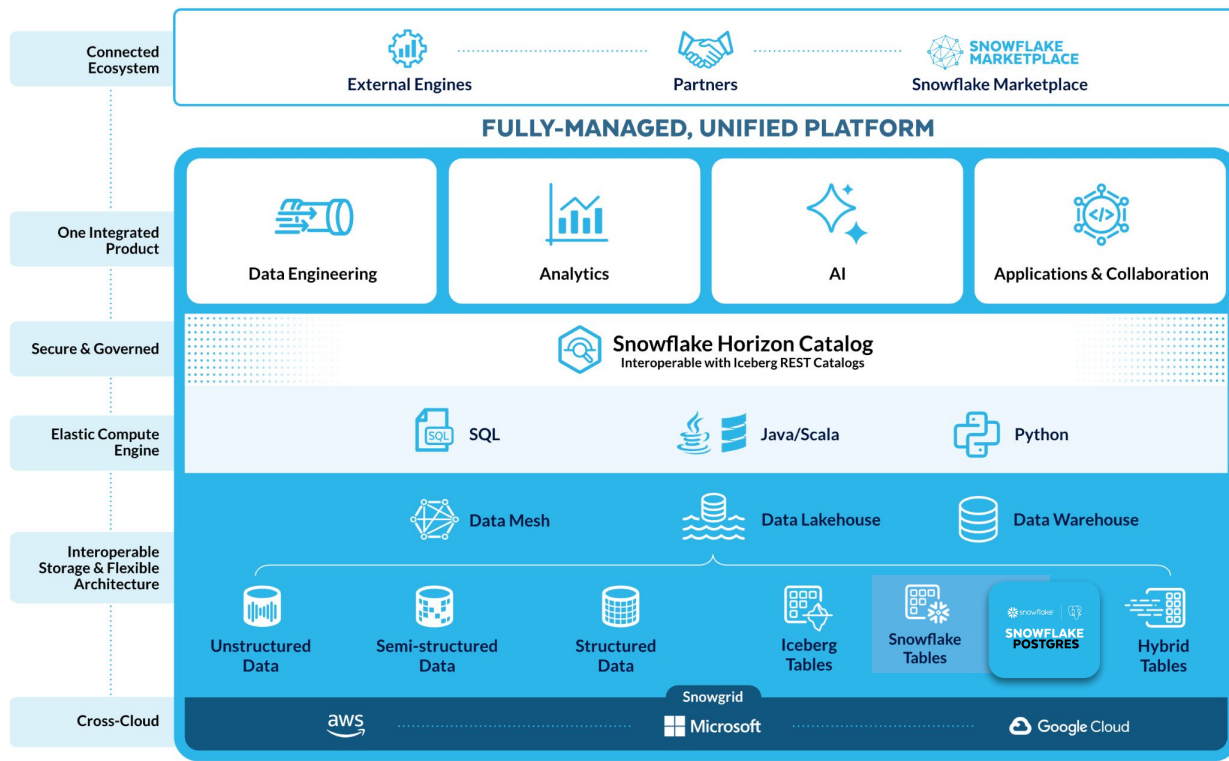

Data Collaboration Concepts

Shares are named Snowflake objects that encapsulate all of the information required to share a database.

A listing is an enhanced method of [Secure Data Sharing](#) and uses the same [provider and consumer model](#).
